

The timing does not fit

Where the shifts actually date

The military sector's position in the network

Left: a common-slope model with one level shift at an unknown date, fitted to each predicted pair. One of the seven dates inside the exposed cohorts, three date to 1700 or 1750 and one to 1400. Read it with care: the model finds the single largest step, so where a series rises early and falls later it reports the fall. That is what happens to politics with the military and politics with administration, both of which do rise across the window and are dated here by their eighteenth-century decline. The safe statement is that no predicted pair has its dominant step inside the window. Right: the military sector does move toward the centre of the network across the exposed cohorts, coreness rising from about 0.3 to 0.9, and stays there. That is the one piece of timing that fits cleanly. Europe only, 25-year birth cohorts. A cohort born in year b has its main career in $[b+25, b+65]$, so the cohorts exposed to a 1560-1660 window are those born between 1495 and 1635; they are held out of the before-and-after contrast, not assigned to a side.
