

The same shape in sixteen revolutions, three centuries apart

revolutions left to right by date; pairs top to bottom by mean association. Hatched cells hold fewer than ten people.

The row order barely disturbs the columns. Ranking each cohort's readable pairs against the pooled ordering gives a Spearman correlation of 0.77 at the median, from 0.35 in the Mexican Revolution to 0.92 in 1848, and no cohort inverts it. Religion with learning and business with learning hold the top of the column and administration with business and administration with religion hold the bottom, in the English Revolution and again in the Iranian one. 85 of these 336 cells hold fewer than ten people and are hatched; they concentrate in the small cohorts, fourteen of the Cuban cohort's twenty-one and none of the German, Russian or 1848 ones.

A cohort is the elites who were adults in a country whose political order was at stake while the revolution ran. Sectors are coarsened to seven groups so a cohort cell has enough cases, and association is refitted inside each cohort, which makes cohorts of very different size comparable. Cells holding fewer than ten people are flagged sparse and dropped from every count, since the score there follows the continuity correction more than the data. These are descriptive cohorts, not treatment groups.
