

Inside a cohort, no consistent divide between the young and the old

Association refitted inside each age band, banded on age at the midpoint of the window. If a revolution recruited a differently structured elite, the youngest band should sit apart from the oldest in a consistent direction. Individual cohorts do separate, by more than a log point in the Russian cohort on politics with the military and on politics with business, but never the same way twice. Across the cohorts where both ends are readable, the 20-35 band differs from the 56+ band by a median of -0.11 on politics with administration, -0.18 on politics with business, -0.04 on politics with the military and +0.15 on politics with learning, and the sign flips from revolution to revolution in every one of the four. Bands below the hundred-pair floor are absent, which is why the small cohorts show one or two points. The under-20 band, whose members reached adulthood inside the window, is left out because it is not the same age range in a two-year revolution and a fifteen-year one. A cohort is the elites who were adults in a country whose political order was at stake while the revolution ran. Sectors are coarsened to seven groups so a cohort cell has enough cases, and association is refitted inside each cohort, which makes cohorts of very different size comparable. Cells holding fewer than ten people are flagged sparse and dropped from every count, since the score there follows the continuity correction more than the data. These are descriptive cohorts, not treatment groups. Source: BHHT cross-verified database of notable people (Laouenan et al., Scientific Data 9:290, 2022).
