

The shape of elite power in a revolution, pooled over sixteen of them

What was held together

What was held apart

Node size is the mean share of a cohort holding the field. Every one of the 21 ties is drawn, on the left where the mean runs positive and on the right where it runs negative. The positive side is a chain, not a clique: administration to politics to the military to the nobility on one arm, and learning to religion and to business on the other. Only one tie joins the two arms, the nobility to learning at 0.26, and the cohorts disagree about even that one. Two fields are attached to a single partner and held apart from all five of the others: administration, which goes with politics alone, and religion, which goes with learning alone. The strongest tie of either kind is negative, administration with business at -1.41. Politics with business is dashed because six cohorts call it dissociated and three call it associated. A cohort is the elites who were adults in a country whose political order was at stake while the revolution ran. Sectors are coarsened to seven fields and association is refitted inside each cohort, so cohorts of very different size are comparable. A tie is $\log_2(\text{observed} / \text{expected under quasi-independence})$: positive means the two fields were held by the same people more often than the size of each field implies, negative means less often. Cells holding fewer than ten people are dropped. These are descriptive cohorts, not treatment groups.
