

Sixteen revolutions, the same seven fields, only the ties that stand out from chance

A tie is drawn only where the cohort's own bootstrap separates it from chance after adjustment, so an empty space between two fields means the cohort had too few people to tell, not that the fields were unrelated. Node size is that cohort's share holding the field. The recurring motif is the triangle of politics, administration and the military at the top of each ring and the tie from learning to religion and to business at the bottom; what changes between panels is whether the two arms are joined and how far administration is pushed out. Count the ties with the cohort size in mind: the German ring resolves all twenty-one and the 1848 and Russian rings nineteen, while the Meiji ring resolves four and the Cuban five. That is the estimator finding more in a larger cohort, not elites who were more entangled. A cohort is the elites who were adults in a country whose political order was at stake while the revolution ran. Sectors are coarsened to seven fields and association is refitted inside each cohort, so cohorts of very different size are comparable. A tie is $\log_2(\text{observed} / \text{expected under quasi-independence})$: positive means the two fields were held by the same people more often than the size of each field implies, negative means less often. Cells holding fewer than ten people are dropped. These are descriptive cohorts, not treatment groups.
