

Three checks on the coding

Left: the coded paths do separate countries on the raw mix of military and business elites, ordered as Tilly's typology says and at $p = 0.008$. So the coercion-side nulls are not a failure of the coding. Those states really do produce more soldiers and fewer merchants; what they do not produce is a tighter bond between politics and the military once that difference in size is netted out. Middle: dropping one country at a time, the composite index keeps a p below 0.18 throughout but the means are ordered as predicted in only one of seventeen drops. Right: moving Denmark, Sweden and Germany leaves the capital-side result intact at $p = 0.013$ and changes nothing else. Sectors are coarsened to seven groups so a country and era cell has enough cases. Paths are coded from Tilly's own examples onto the modern states the source uses; the lossiest case is Italy, which merges Venice and Genoa with the papal and southern states. Inference permutes the path labels across countries. Source: BHHT cross-verified database of notable people (Laouenan et al., Scientific Data 9:290, 2022).
